

1. Just rewrite the SP for login and try to return a connection string from a single SP (you can try to join those tables for it).
2. Saving data into those tables should be done through a SP.
3. Just send Two Stored procedures (No need to send the backup database again).
4. We need an msi package not those publish pages that you send. Just create a web setup project and then send to us (Send only those msi files) along with source code (Project code that you have done).
5. Finally please write a technical document and send to us (It is the document for programmers/developers. Through it they can understand how you have designed it).
